The **copy constructor** is a constructor which creates an object by initializing it with an object of the same class, which has been created previously. The copy constructor is used to:

- Initialize one object from another of the same type.
- Copy an object to pass it as an argument to a function.
- Copy an object to return it from a function.

If a copy constructor is not defined in a class, the compiler itself defines one. If the class has pointer variables and has some dynamic memory allocations, then it is a must to have a copy constructor. The most common form of copy constructor is shown here:

```
classname (const classname &obj) {  
    // body of constructor  
}
```

Here, **obj** is a reference to an object that is being used to initialize another object.

```
#include <iostream>  
  
using namespace std;  
  
class Line  
{  
public:  
    int getLength( void );  
    Line( int len );           // simple constructor  
    Line( const Line &obj);    // copy constructor  
    ~Line();                  // destructor  
  
private:  
    int *ptr;  
};  
  
// Member functions definitions including constructor  
Line::Line(int len)  
{  
    cout << "Normal constructor allocating ptr" << endl;  
    // allocate memory for the pointer;  
    ptr = new int;  
    *ptr = len;  
}  
  
Line::Line(const Line &obj)  
{  
    cout << "Copy constructor allocating ptr." << endl;  
    ptr = new int;  
    *ptr = *obj.ptr; // copy the value  
}  
  
Line::~~Line(void)  
{  
    cout << "Freeing memory!" << endl;  
    delete ptr;  
}  
  
int Line::getLength( void )  
{  
    return *ptr;  
}  
  
void display(Line obj)  
{  
    cout << "Length of line : " << obj.getLength() << endl;
```

```

}

// Main function for the program
int main( )
{
    Line line(10);

    display(line);

    return 0;
}

```

When the above code is compiled and executed, it produces the following result:

```

Normal constructor allocating ptr
Copy constructor allocating ptr.
Length of line : 10
Freeing memory!
Freeing memory!

```

Let us see the same example but with a small change to create another object using existing object of the same type:

```

#include <iostream>

using namespace std;

class Line
{
public:
    int getLength( void );
    Line( int len );           // simple constructor
    Line( const Line &obj);    // copy constructor
    ~Line();                  // destructor

private:
    int *ptr;
};

// Member functions definitions including constructor
Line::Line(int len)
{
    cout << "Normal constructor allocating ptr" << endl;
    // allocate memory for the pointer;
    ptr = new int;
    *ptr = len;
}

Line::Line(const Line &obj)
{
    cout << "Copy constructor allocating ptr." << endl;
    ptr = new int;
    *ptr = *obj.ptr; // copy the value
}

Line::~~Line(void)
{
    cout << "Freeing memory!" << endl;
    delete ptr;
}

int Line::getLength( void )
{
    return *ptr;
}

void display(Line obj)
{
    cout << "Length of line : " << obj.getLength() << endl;
}

// Main function for the program

```

```
int main( )
{
    Line line1(10);

    Line line2 = line1; // This also calls copy constructor

    display(line1);
    display(line2);

    return 0;
}
```

When the above code is compiled and executed, it produces the following result:

```
Normal constructor allocating ptr
Copy constructor allocating ptr.
Copy constructor allocating ptr.
Length of line : 10
Freeing memory!
Copy constructor allocating ptr.
Length of line : 10
Freeing memory!
Freeing memory!
Freeing memory!
```
